(54) Title: METHOD FOR DEWATERING MUNICIPAL WASTE-ACTIVATED SLUDGE USING HIGH ELECTRICAL VOLTAGE

(57) Abstract: A system that allows the flexibility of primary and secondary treatment of municipal sludge, paper-pulp sludge, animal and plant waste, whereby the treatment thereof via electroporation may be used either as the primary dewatering treatment, secondary dewatering treatment, direct WAS-treatment, and combinations with other conventional dewatering techniques, in order to provide the municipal treatment plant, or the paper-pulp treatment plant, with the most cost-effective and efficient system as possible. The electroporated-treated sludge releases hitherto unreleased biosolids exiting from the PEF-electroporation system, which are returned to aeration tanks. The electroporation process causes the release of intracellular dissolved/organic matter, which is used as "food" for the bacteria of the aeration tanks.

METHOD FOR DEWATERING MUNICIPAL WASTE-ACTIVATED SLUDGE USING HIGH ELECTRICAL VOLTAGE

BACKGROUND OF THE INVENTION

In U.S. Patent No. 6,030,538, issued in February 29, 2000 entitled "Method and Apparatus for Dewatering Previously-Dewatered Municipal Waste-Water Sludges Using High Electrical Voltages, there is disclosed a system and method for dewatering and treating waste-activated sludge (WAS) emanating from municipal waste, or pulp-waste from a paper mill, as well as treating animal and plant waste. In that patent, the method for breaking down the WAS is to subject the WAS to electroporation, which incorporates nonarcing, cyclical high voltages in the range of between 15 KV and 100 KV, which break down inter-cellular and intracellular molecular bonds, to thus release inter-cellular and intracellular water, whereby the WAS is rendered inactive and greatly reduced in mass.

In the above-noted U.S. Patent, the apparatus and method disclosed therein, while capable in certain circumstances of being a primary municipal-sludge treatment, its intended and main objective was to use it as a secondary treatment to previously-dewatered municipal waste sludge. It is the goal of the present invention to adapt the method and apparatus of U.S. Patent No. 6,030,538, issued in February 29, 2000 entitled "Method and Apparatus for Dewatering Previously-Dewatered Municipal Waste-Water Sludges Using High Electrical Voltages into a main, primary treatment of municipal waste sludge.

In a previous (Phase I) project, it has been demonstrated the laboratory feasibility of pulsed electric field (PEF) for disrupting the biomass in waste activated

sludge (WAS) derived from municipal wastewater treatment. While there was no significant increase in the solids content of dewatered sludge, the quantity of WAS needing disposal was estimated to be significantly reduced.

Encouraged by the Phase I results, a pilot plant for testing at one or two wastewater treatment plants that generate WAS has been developed. It has been decided that a pulsed electric field (PEF) system that could handle 0.5 to 1.0 pgm WAS feed be designed. This requires an 8 kw power supply capable of generating 30 kV and pulse generator capable of handling 50 amp peak, current, bi-polar pulses, square wave, 10 μ s pulse width, and 3000 pulses/second (pps).

SUMMARY OF THE INVENTION

It is the primary objective of the present invention to provide a method and apparatus for dewatering municipal waste sludge, paper-pulp waste sludge, animal and plant waste, using electroporation for the primary treatment of the sludge.

It is also a primary objective of the present to provide such a system that will allow flexibility as to the primary and secondary treatment of municipal sludge, paper-pulp sludge, animal and plant waste, whereby the treatment thereof via electroporation may be used either as the primary dewatering treatment, secondary dewatering treatment, direct WAS-treatment, and combinations with other conventional dewatering techniques, in order to provide the municipal treatment plant, or the paper-pulp treatment plant, with the most cost-effective and efficient system as possible.

BRIEF DESCRIPTION OF THE DRAWING

The invention will be more readily understood with reference to the accompanying drawings, wherein:

Figure 1 is a schematic showing the electroporation system as used as a secondary dewatering treatment;

Figure 2 is a schematic showing the electroporation system used in conjunction as a primary dewatering treatment in accordance with the present invention;

Figure 3 is a schematic showing the electroporation sub-system for use in dewatering municipal, paper-pulp, animal and plant waste sludges; and

Figure 4 is a schematic diagram showing the overall apparatus of the present invention incorporating the electroporation sub-system for use as a primary or secondary dewatering treatment.

DETAILED DESCRIPTION OF THE INVENTION

The original concept for the pulsed-electric field (PEF) effect using electroporation was to dewater the previously-dewatered sludge. However, additional PEF data on a paper plant sludge has indicated that the big PEF effect from electroporation of WAS occurs at higher energy levels (e.g., 100 J/mL; or 400 k Wh/ton (DS) for feed at 6 percent solids), whereby cells are disrupted. The result is inactivation of cells, breakage of cells and release of some intracellular dissolved/organic matter and typically a worsening of flocculation and dewatering. Therefore, a more effective way of using this process is to recycle all of the PEF-treated sludge back to a aerobic bioreactor to utilize the sludge as food; that is, it has

been discovered that the PEF-electroporation effect on disrupting the cellular units of the WAS has been to release intracellular dissolved/organic matter. This intracellular dissolved/organic matter is just the type of ideal "food" upon which the aerobic bioreactor flourishes. Thus, returning this released intracellular dissolved/organic matter back to the aerobic bioreactor will increase the BOD load on the bioreactor, and will thus reduce the quantity of WAS by up to about 50 percent. The flow sheet for this scenario is shown in Figure 2. Thus, it is now practical to employ the PEF-electroporation system as not only a secondary system for treating previously-dewatered sludge, but also to employ it as a primary system, as described hereinbelow.

Referring to Fig. 1, there is shown the schematic for using the PEF-electroporation system as a secondary treatment for previously-dewatered sludge, as disclosed in U.S. Patent No. 6,030,538, issued in February 29, 2000 entitled "Method and Apparatus for Dewatering Previously-Dewatered Municipal Wastewater Sludges Using High Electrical Voltages. In Fig. 1, the wastewater is delivered to the primary treatment, aerobic-reactor tanks 10, and from there to a secondary clarifier 12. From there, the WAS is delivered to the PEF-electroporation system 14 of the invention for deactivating the WAS to make it a Class "B" biomass for easier disposal. The biomass is then sent to a belt press 16 for further processing and disposal.

Referring now to Fig. 2, there is shown the flow chart of the present invention for employing the PEF-electroporation system as part of the primary treatment. In this system, the biosolids exiting from the PEF-electroporation system 14 are returned to the aeration tanks 10, since, as explained above, the PEF process

causes the release of intracellular, dissolved organic matter, which is used as "food" for the bacteria of the aeration tanks. This "food" not only is further treated in the aeration tanks via aerobic digestion, but actually causes the aerobic digestion process in the aerobic tank itself to be accelerated for the same amount of oxygen supplied.

A practical problem with the system of Figure 2 is that the PEF throughput needs to be of the same order of magnitude as the WAS disposal rate in order to see a noticeable effect of PEF on WAS reduction. For this reason a 1.8 ton (DS)/day PEF system has been chosen as a pilot plant. With such a system, a WAS reduction of 0.9 ton/day on a dry basis or 7.5 tons/day on a filter press cake (at 12 percent solids) basis may be achieved. In terms of thickened sludge (at 2 percent solids) basis, this translate to elimination of 45 tons/day needing to be flocculated and dewatered. This will require PEF treatment of 15 gpm WAS at 2 percent solids.

One way to reduce the cost of the pilot plant, which is driven by the PEF power supply and pulser cost, is to pre-thicken the WAS. Therefore, a 15 gpm rental centrifuge 18 is used for pilot testing. It is estimated that this will produce a 5 gpm feed for the PEF reactor at a solids content of 6 percent. Such a feed can be handled by a Moyno pump. The feed streams to the centrifuge and the PEF units are represented as Stream Nos. 10 and 11, respectively in Figure 2. However, in practical application such as centrifuge may not be necessary.

PEF POWER SUPPLY AND PULSER DESIGN

The conceptual design of the power supply and the pulse generator (pulser) for the system of Fig. 2 is shown in Figure 3. This figure shows four chambers 20 in

series, although two chambers also can be used if the pulse rate is increased. The specifications for the two-chamber design are shown in Table 1. The design requires a 35 kW input power supply 22 (32 kW continuous output) delivering 30 kV. The pulse generator 24 is 200 amp maximum current and a pulse rate of 4,000 hz. (maximum).

The actual sludge handling system and the associated instrumentation is shown in Figure 4. A detailed list of specifications is provided in Table 2. Tank T1 holds up to 100 gallons of untreated feed material, delivered through valve V1 from the centrifuge 18. A mixer is provided for blending infeed material. A bottom drain allows disposal to sewer at the end of a test run. Valve V4 is provided for withdrawing a sample for analysis. Material leaves T1 through V2 and a strainer to a variable-speed progressing cavity pump, which can flow from 0.5 to 5.0 gallons per minute. The tank, pump mixer and associated valves are mounted to one 42-inch square skid for transport purposes. The feed leaving P1 passes through quick-connect fittings to a reinforced hose to the reactor.

The PEF-electroporation reactor subsystem includes a power supply, pulse generator and pairs of treatment chambers as described above with reference to Fig. 3. These would be mounted to a skid, along with associated valves V5, 6 and 7. Quick-connect fittings and hose convey the treated material to valves on the outlet tank skid. Valves V12 and 13 permit the treated material to be recycled back to T1. Valve V8 permits the treated material to enter tank T2, of 100-gallon capacity. As with T1, a mixer, a sample port and a bottom drain are provided. Tank T2, pump P2, mixer M2 and associated valves are mounted to another skid. Treated material leaving through V10 leads to transfer pump P2. Valve V18 is a globe style for adjusting the flow rate through V14 to tank T3. Valve V13 allows treated material from T2 to return to T1, assisted by P2, to increase treatment time.

The P2 pump is used to return the treated sludge to the biotreatment plant, aerobic tanks 10, when the PEF-electroporation system is used as a primary system,

or optionally to filter press 16, if desired, when the PEF-electroporation system is used as a secondary treatment.

Safety logic has been incorporated as follows. Level control L1 will close V1 to prevent overfilling T1, with subsequent spillage. Level control L2 will shut down P1 and the power supply when the liquid level becomes too low. Level control L3 and T2 will shut down P1 and the power supply when tank T3 becomes full, to prevent spillage.

While a specific embodiment of the invention has been shown and described, it is to be understood that numerous changes and modifications may be made therein without departing from the scope and spirit of the invention as set forth in the appended claims.

WHAT WE CLAIM IS:

CLAIM 1. A method of dewatering paper-pulp sludge, municipal waste sludge, animal waste sludge containing intra-cellular water molecules contained in molecular cellular units of the waste sludge, or plant and animal waste sludge, comprising:

- (a) pumping the waste sludge into a dewatering apparatus;
- (b) destroying in the dewatering apparatus at least most of the individual cellular units of the waste sludge in order to release the intra-cellular water molecules contained therein; and

said step (b) causing massive disruption of the cellular matter, allowing for the release of bound as well as intra-cellular liquids and intracellular dissolved/organic matter, which may be used as food for the bacteria of aeration tanks;

- (c) directing the released intracellular dissolved/organic matter to an aeration tank for supplying food to bacteria of said aeration tank.

CLAIM 2. The method according to claim 1, wherein said step (b) comprises electroporating said sludge.

CLAIM 3. The method according to claim 2, wherein said electroporation is performed with voltages between 15 KV. and 100,00 KV.

CLAIM 4. A method of treating sludge, such as paper-pulp sludge, municipal sludge, plant and animal waste, in which the sludge is treated in an aeration tank for performing aerobic digestion, comprising:

(a) treating the sludge to a dewatering process that releases intracellular dissolved/organic matter;

(b) directing the sludge treated in said step (a) to an aeration tank for performing aerobic digestion thereon

whereby the intracellular, dissolved organic matter is used as food for the bacteria of the aeration tanks, whereby the aerobic digestion process is accelerated thereby for the same amount of supplied oxygen.

CLAIM 5. The method according to claim 4, wherein said step (a) comprises electroporating the sludge.

CLAIM 6. The method according to claim 4, further comprising alternatively directing the sludge directly to a further dewatering process.

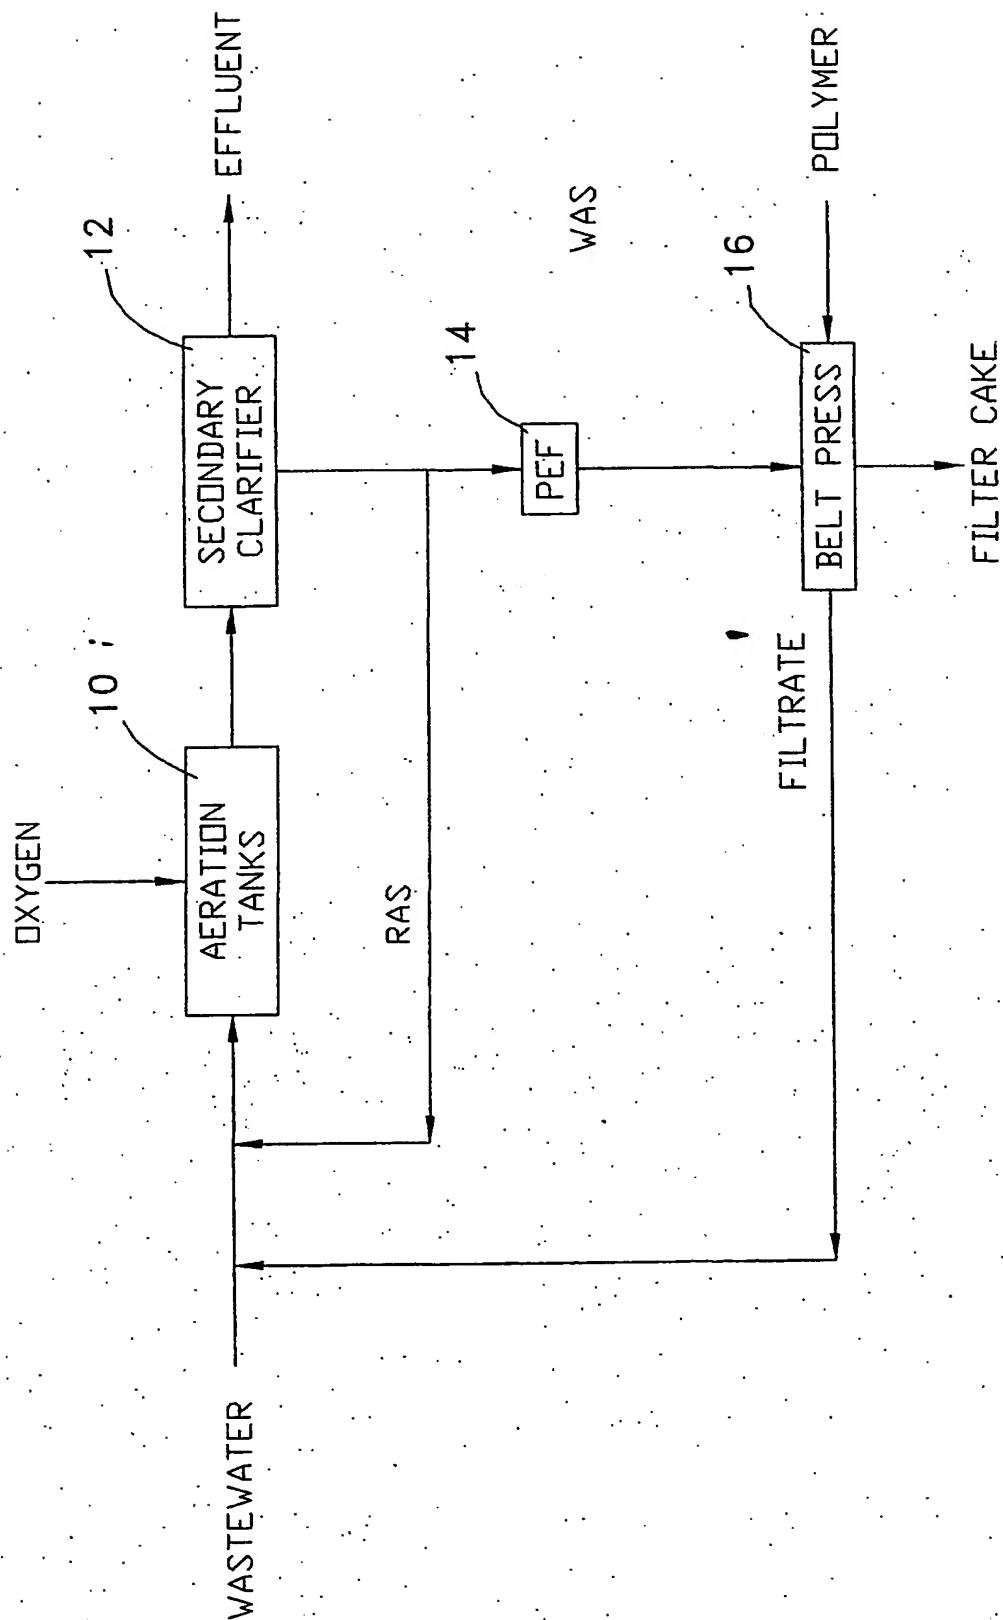

CLAIM 7. A method of treating sludge, such as paper-pulp sludge, municipal sludge, plant and animal waste,

(a) treating the sludge to a dewatering process that releases intracellular, dissolved organic matter;

(b) directing the sludge treated in said step (a) to one of: an aeration tank for performing aerobic digestion thereon, or to a different, dewatering process.

CLAIM 8. The method according to claim 7, wherein said step (b) comprises alternatively directing the sludge to further dewatering process consisting of a filter press.

CLAIM 9. The method according to claim 7, wherein said (b) comprises directing the sludge to an aeration tank, where said intracellular, dissolved organic matter is used as food for the bacteria of the aeration tanks, whereby the aerobic digestion process is accelerated thereby for the same amount of supplied oxygen.
